

SESSION 4 – API Testing (Basic Intro) + Database SQL Testing

1. GET API Request Testing

Ans:

- Sent a GET request to `/api/users/2` using ReqRes.
- Response status code received: **200 OK**.
- User details were returned successfully.
- First name of the user received in the response: **Janet**.

2. POST API Request Testing

Ans:

- Sent a POST request to `/api/users` with the following JSON data:

```
{ "name": "Virat", "job": "Cricketer" }
```
- Response status code received: **201 Created**.
- A unique ID was generated in the response.
- User data was created successfully.

3. SQL INSERT Query

Ans:

```
INSERT INTO restaurants (id, name, location)
VALUES (101, 'Pizza Hut', 'Ahmedabad');
```

- The query inserts a new restaurant record into the restaurants table.
- All values are mapped to their respective columns correctly.

4. SQL SELECT Query for User Verification

Ans:

```
SELECT *  
FROM users  
WHERE name = 'Riya';
```

- This query checks whether the user “Riya” exists in the database.
- If the UI and database are synchronized, one matching record should be returned.
- If no record is found, it may indicate a data synchronization issue.

5. SQL Query to Verify Product Deletion

Ans:

```
SELECT *  
FROM cart_items  
WHERE product_id = 101  
AND user_id = 1001;
```

- Executed the query after removing the product from the shopping cart.
- No records should be returned if the deletion was successful.
- An existing record would indicate that the product was not removed properly from the database.

Result:

API and database testing activities were completed successfully. GET and POST requests returned expected responses, and SQL queries correctly verified data insertion, retrieval, and deletion operations.
